In 46 patients residents of Yakutia with destructive forms of pulmonary tuberculosis changes of respiratory function on the background of long-term treatment with an ACE inhibitor Enap 5mg were studied. It was found that Enap 5mg prolonged use (over 2 years) does not cause bronchial obstruction during the compensated tuberculosis, in the presence of initially moderate violations of pulmonary ventilation capacity against the background of chemotherapy in 50% of patients leads to improvement or partial improvement of ventilatory function.

Keywords: destructive forms of pulmonary tuberculosis, pulmonary ventilation.
